IMPLEMENT THE MAX TEMPERATURE MAPREDUCE PROGRAM TO IDENTIFY THE YEAR WISE MAXIMUM TEMPERATURE FROM SENSOR

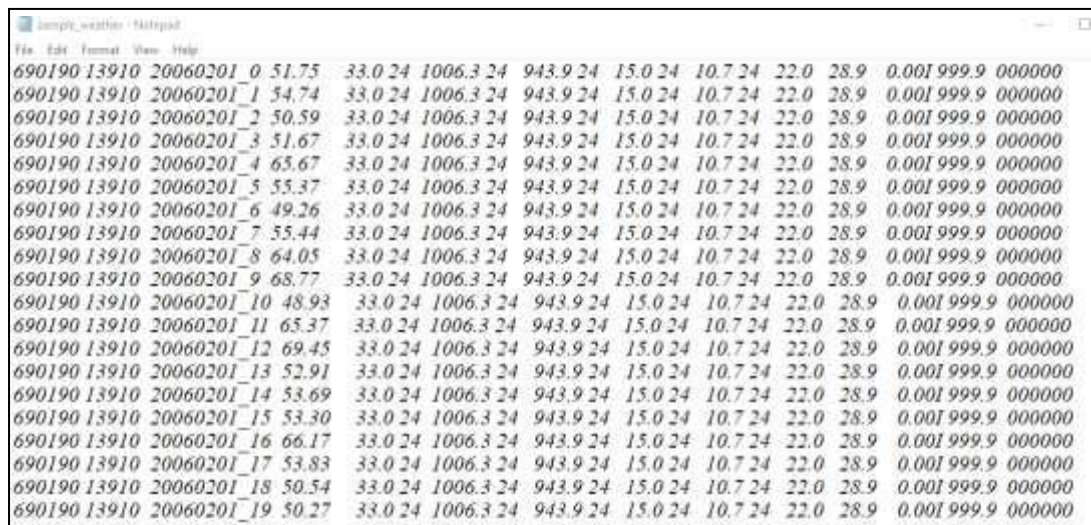

AIM:

To implement the max temperature Mapreduce program to identify the year wise maximum temperature from sensor.

PROCEDURE:

Step 1: Create Data File:

Create a file named "sample_weather.txt" and populate it with text data that you wish to analyse.

Step 2: Mapper Logic - mapper.py:

Create a file named "mapper.py" to implement the logic for the mapper. The mapper will read input data from STDIN, split lines into words, and output each word with its count.

mapper.py:

```
#!/usr/bin/python3
import sys
def map1():
    for line in sys.stdin:
        tokens = line.strip().split()
        if len(tokens) < 13:
            continue
        station = tokens[0]
        if "STN" in station:
            continue
        date_hour = tokens[2]
        temp = tokens[3]
        dew = tokens[4]
        wind = tokens[12]
        if temp == "9999.9" or dew == "9999.9" or wind == "999.9":
            continue
```

```

hour = int(date_hour.split("_")[-1])
date = date_hour[:date_hour.rfind("_")-2]
if 4 < hour <= 10:
    section = "section1"
elif 10 < hour <= 16:
    section = "section2"
elif 16 < hour <= 22:
    section = "section3"
else:
    section = "section4"
key_out = f"{station}_{date}_{section}"
value_out = f"{temp} {dew} {wind}"
print(f"{key_out}\t{value_out}")
if __name__ == "__main__":
    map1()

```

Step 3: Reducer Logic - reducer.py:

Create a file named "reducer.py" to implement the logic for the reducer. The reducer will aggregate the occurrences of each word and generate the final output.

reducer.py:

```

#!/usr/bin/python3
import sys
def reduce1():
    current_key = None
    sum_temp, sum_dew, sum_wind = 0, 0, 0
    count = 0
    for line in sys.stdin:
        key, value = line.strip().split("\t")
        temp, dew, wind = map(float, value.split())
        if current_key is None:
            current_key = key
        if key == current_key:
            sum_temp += temp
            sum_dew += dew
            sum_wind += wind
            count += 1
        else:
            avg_temp = sum_temp / count
            avg_dew = sum_dew / count
            avg_wind = sum_wind / count
            print(f"{current_key}\t{avg_temp} {avg_dew} {avg_wind}")

            current_key = key
            sum_temp, sum_dew, sum_wind = temp, dew, wind
            count = 1
    if current_key is not None:
        avg_temp = sum_temp / count
        avg_dew = sum_dew / count
        avg_wind = sum_wind / count
        print(f"{current_key}\t{avg_temp} {avg_dew} {avg_wind}")

```

```
if __name__ == "__main__":  
    reduce1()
```

Step 4: Prepare Hadoop Environment:

Start the Hadoop daemons and create a directory in HDFS to store your data. Run the following commands to store the data in the WeatherData Directory.

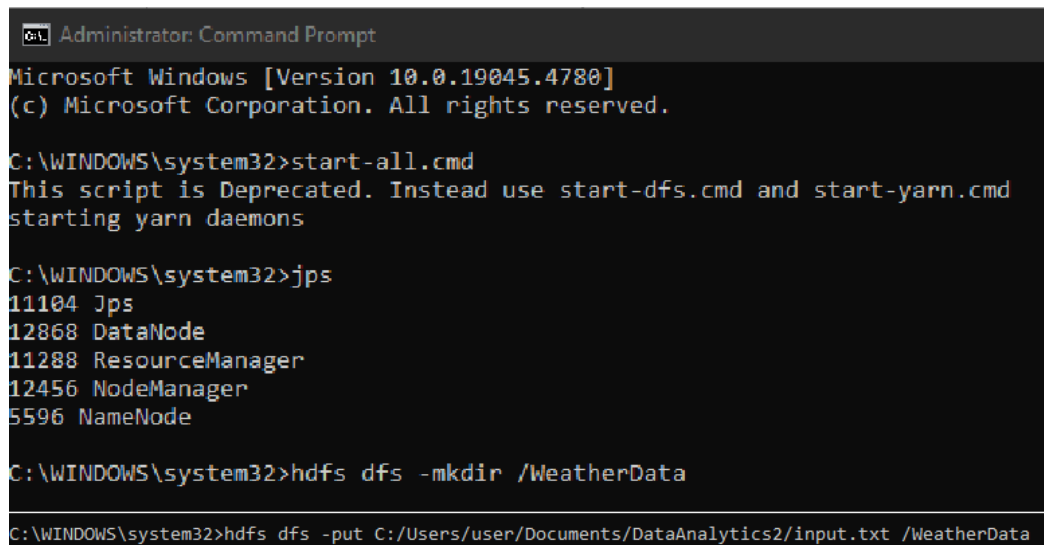

```
start-all.cmd  
cd C:/Hadoop/sbin  
hdfs dfs -mkdir /WeatherData  
hdfs dfs -put C:/Users/user/Documents/DataAnalytics2/input.txt /WeatherData  
hadoop jar C:\hadoop\share\hadoop\tools\lib\hadoop-streaming-3.3.6.jar ^  
-input /user/input/sample_weather.txt ^  
-output /user/output ^  
-mapper "python C:/Users/user/Documents/DataAnalytics2/mapper.py" ^  
-reducer "python C:/Users/user/Documents/DataAnalytics2/reducer.py"
```

Step 5: Check Output:

Check the output of the Word Count program in the specified HDFS output directory.

```
hdfs dfs -cat /WeatherData/output/part-00000
```

OUTPUT:

```
Administrator: Command Prompt  
Microsoft Windows [Version 10.0.19045.4780]  
(c) Microsoft Corporation. All rights reserved.  
  
C:\WINDOWS\system32>start-all.cmd  
This script is Deprecated. Instead use start-dfs.cmd and start-yarn.cmd  
starting yarn daemons  
  
C:\WINDOWS\system32>jps  
11104 Jps  
12868 DataNode  
11288 ResourceManager  
12456 NodeManager  
5596 NameNode  
  
C:\WINDOWS\system32>hdfs dfs -mkdir /WeatherData  
  
C:\WINDOWS\system32>hdfs dfs -put C:/Users/user/Documents/DataAnalytics2/input.txt /WeatherData
```
